

Class 0 · Think, test, explain.

Student + partner · Paper and pencil are enough. Students explain first.

1 · Program your human robot

A3	B3	C3 · GOAL
A2	B2 · WALL	C2
A1 · START	B1	C1

E: one cell east (right).

N: one cell north (up).

Start at A1. Reach C3 in four commands.

Stay on the board; stop at a wall.

Student writes. Partner executes exactly. Swap roles.

My four commands:

What happened? Where did the route end?

New input: move the wall from B2 to C2 and restart at A1.

My prediction for the same commands, and why:

The actual result. If it failed, what would I change?

2 · What could AI help you do?

One useful task for AI:

One decision I would make and check myself:

Class 0 · Check the lamp rule.

Requirement: below 30 → Lamp ON. At 30 or above → Lamp OFF.
Simulated integer input: 0–100. No physical lamp is connected.

Draft below: a classroom-made simulation of an AI suggestion, not an actual AI transcript.

```
# Simulated brightness: 0 = dark, 100 = bright
brightness = 10
if brightness <= 30:
    print("Lamp ON")
else:
    print("Lamp OFF")
```

First: fill the prediction column. **Then:** run and inspect.

Brightness	Expected	Draft result	After repair
10			
50			
30			
0			
100			

Evidence method: ☐ Python ☐ Rule simulator ☐ Manual trace

The mismatch, my change, and why it meets the requirement:

Exit ticket · Your own words

Why was 30 useful to test?

I want to build or explore... My first test would be...

Partner: one decision I saw the student make today:
